Central Electricity Authority
Long-Term National Resource Adequacy Plan
2026-27 - 2035-36

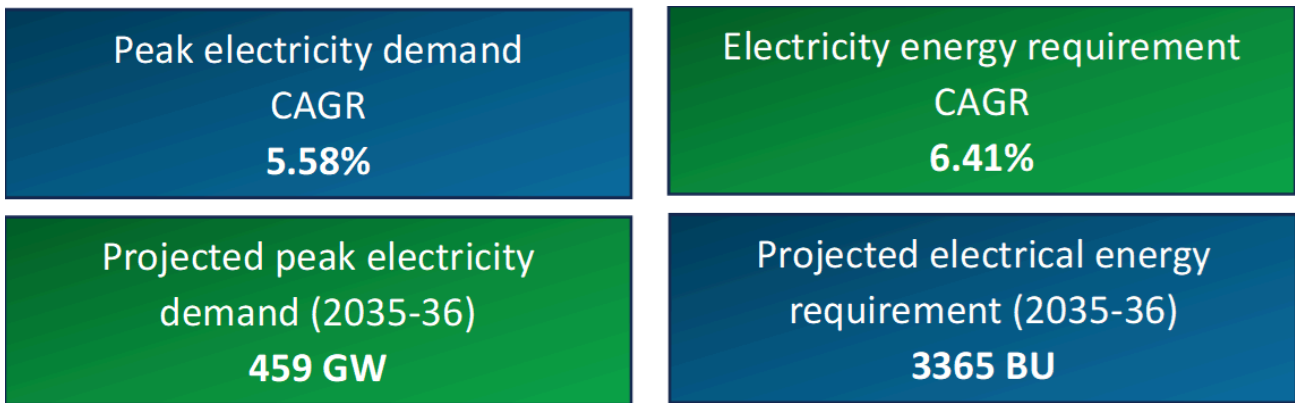

Background and Introduction

The transition towards green energy has gained momentum in the past two decades. Countries are optimizing their energy generation to reduce carbon emissions and mitigate climate change impacts. Energy alternates that are non-fossil fuel based such as solar, wind, hydro, nuclear and geothermal; assisted by Energy Storage Systems are the primary choices of countries.

India's commitment towards the green energy transition has been demonstrated with a record 43 GW of generation capacity installed in 2025-26 up to January 2026 from renewable energy sources.

The Long-term National Resource Adequacy Plan (LT-NRAP) is developed by the Central Electricity Authority under the notified Electricity (Amendment) Rules 2022, Rules 16 (1) stipulating to assess the adequacy of electricity resources over a ten-year planning horizon with a purpose to facilitate coordinated planning, policy formulation, and investment decisions.

Key Projections

The CAGR has been calculated for the period of 2024-25 to 2035-36. The 20th Electric Power Survey has been utilised for these projections

Definitions

- Resource Adequacy** is defined as a mechanism to ensure an adequate supply of generation resources to reliably meet the projected electricity demand at the least cost. A crucial aspect of resource adequacy planning is ensuring that sufficient generation capacities are available round the clock, capable of reliably serving electricity demand under various scenarios, while considering factors such as extreme weather events, plant availability, etc.
- Coincident Peak** refers to the share of different distribution utilities in the national peak demand. The occurrence of peak demand varies across months and times of day. Therefore, the top 5% or 10% of demand hours of the national load should be considered for the determination of the coincident peak.
- Capacity Credit** refers to the dependable contribution of a power source or generation technology to meet peak electricity demand reliably. It is typically expressed as a percentage of the nameplate capacity that can be counted on during peak demand periods.

| Source | Capacity Credit (Solar Hours) | Capacity Credit (Non -Solar Hours) |
|---------------|-------------------------------|------------------------------------|
| Coal | 0.8 | 0.8 |
| Gas | 0.3 | 0.5 |
| Nuclear | 0.7 | 0.7 |
| Hydro | 0.5 | 0.6 |
| Biomass & MSW | 0.2 | 0.2 |

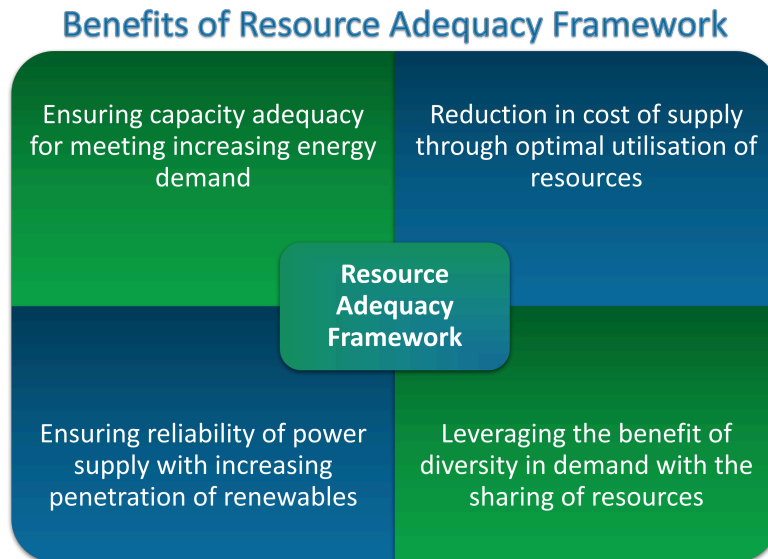

Note: A lower value of the capacity credit of Gas based Generation during solar hours has been considered based on the historical trend of utilisation of gas-based generation. In case of availability of gas, a higher value may be considered.

Objective and Methodology

Through LT-NRAP CEA envisages to minimize the total system cost of generation (including future investment costs, operating costs of generation fleet and others) while ensuring that all the technical parameters associated with different technologies are satisfied.

CEA has utilised the mid-term review of the 20th Electric Power Survey to estimate electricity demand projections, peak electricity demand growth rates and electricity energy requirement growth rates.

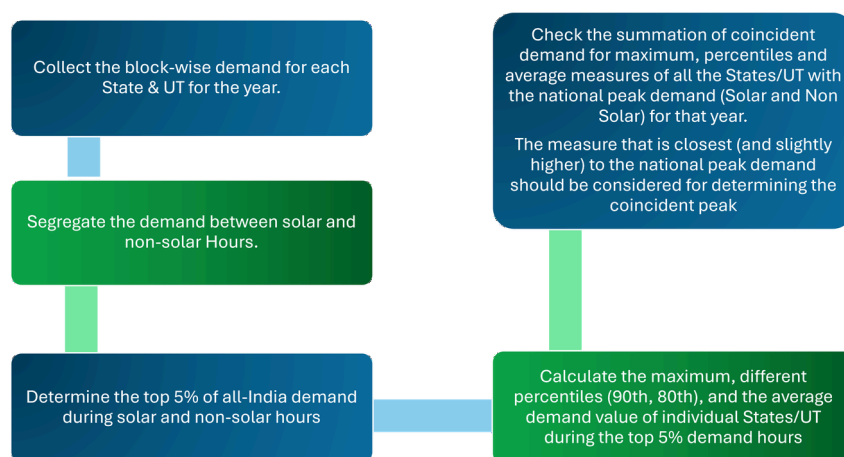

As part of the Resource Adequacy Planning framework, State-wise coincident peak requirement for 2026-27 and 2027-28 with generator-source-wise capacity credit has been estimated. Year-wise solar and non-solar Planning Reserve Margin (PRM) has also been estimated.

Key aspects in the methodology are as follows:

- **Electricity Demand Projection:** A detailed demand projection using historical data, economic growth models, and demographic projections. This includes estimating State-wise peak electricity demand and annual electrical energy requirements for multiple timeframes, typically spanning twenty years.
- **Generation Capacity Assessment:** This considers existing capacity, new capacity additions, potential retirements and upgrades to ensure that the generation mix is able to meet the projected electricity demand in different scenarios.
- **Optimisation and Sensitivity Analysis:** Optimisation techniques, such as MILP (Mixed Integer Linear Programming), linear programming and Monte Carlo simulations, are used to identify the most cost-effective and reliable energy mix. Sensitivity analysis is conducted to evaluate the system’s resilience to variations in electricity demand.
- **Policy and Regulatory Alignment:** Incorporates national policies, such as renewable energy targets, electrification goals, etc., ensuring that the proposed plans align with long-term policy objectives.
- **Stakeholder Engagement:** Discussions are carried out with stakeholders such as government agencies, utilities, industry associations, etc., to ensure that all perspectives are considered in the plan.

Methodology to calculate coincident peak

- **Loss of Load Probability (LOLP)** is the probability that projected electricity demand will exceed available generation capacity.
- **Expected Energy Not Served (EENS)** is the amount of energy demand that cannot be met due to insufficient generation.

- **Planning Reserve Margin (PRM)** represents the total available firm capacity above the expected peak demand to ensure reliability in the face of uncertainties. Estimating PRM is essential for maintaining system adequacy, especially as power systems integrate more variable resources like renewables.

Fundamental steps involved in Resource Adequacy study

- **Generation Expansion Planning Studies** are the process to evaluate the most economically feasible generation capacity additions to meet the projected electricity demand. It takes into account factors such as the electricity demand projection, existing and planned capacity additions, evolving demand patterns, renewable energy profiles, cost trends of various investment options, operational characteristics of different generation technologies, phasing out of older capacity, etc.
- **Production Cost Analysis** also known as Economic Dispatch studies, is essential to carry out economic (least-cost) dispatch, adhering to unit commitment and other model inputs and constraints. This is typically carried out for a 1-year horizon with the time interval of Hourly (60 min)/sub-hourly (15 min) resolution. It gives information about the following:
 - Generator-wise annual generation, fuel cost, start-up cost, etc
 - Start- Stop of thermal generators
 - Renewable energy curtailment, if any
 - Unserved Energy- demand blocks
 - Reserve Requirement in the system
 - Ramping Constraints of thermal generators
- **System Reliability Analysis** involves the use of advanced probabilistic methods, such as Monte Carlo simulation and stochastic modelling, to capture the uncertainties that impact the power system. The analysis allows for the estimation of key reliability indices such as LOLP and EENS. These methods help evaluate how the system behaves under various uncertain conditions, including:
 - Scheduled and unscheduled outages or maintenance of generating units
 - Unforeseen fluctuations in renewable energy (RE) generation
 - Unexpected changes in electricity demand
 - Variations in hydroelectric generation, depending on hydrological conditions
- **ORDENA**, a mixed-integer linear optimisation model that minimises the net present value of investment and operating costs subject to constraints and **STELLAR**, an indigenous generation expansion planning tool that integrates long-term capacity planning, economic dispatch, and reliability analysis into a unified framework are the Generation Expansion Planning Tools.

Demand Complementarity and Correlation among States

- **Demand complementarity** refers to the compensating or balancing relationship between the electricity demand of different States where an increase in demand in one State coincides with a decrease or lower demand in another.
- **Demand correlation** denotes the statistical degree of association between electricity demand patterns across sectors, regions, or time intervals. A positive correlation indicates that the demands in different States move in the same direction, such as electricity demand in hilly States in the winter months.
- Analysing demand correlation both spatially (across regions) and temporally (across time) allows system planners to identify divergent demand patterns, assess load diversity, and design strategies that ensure reliable and balanced power system operation.

- States with high positive correlation exhibit similar demand patterns, indicating limited potential for resource sharing or banking. Conversely, States with low or negative correlation demonstrate complementary demand profiles, which can be leveraged to enhance system reliability through coordinated resource planning or banking.

Source Wise Gross Generation (BU) 2025-26
(as on 31.01.2026)

Source wise projected gross generation (BU) in 2035-36

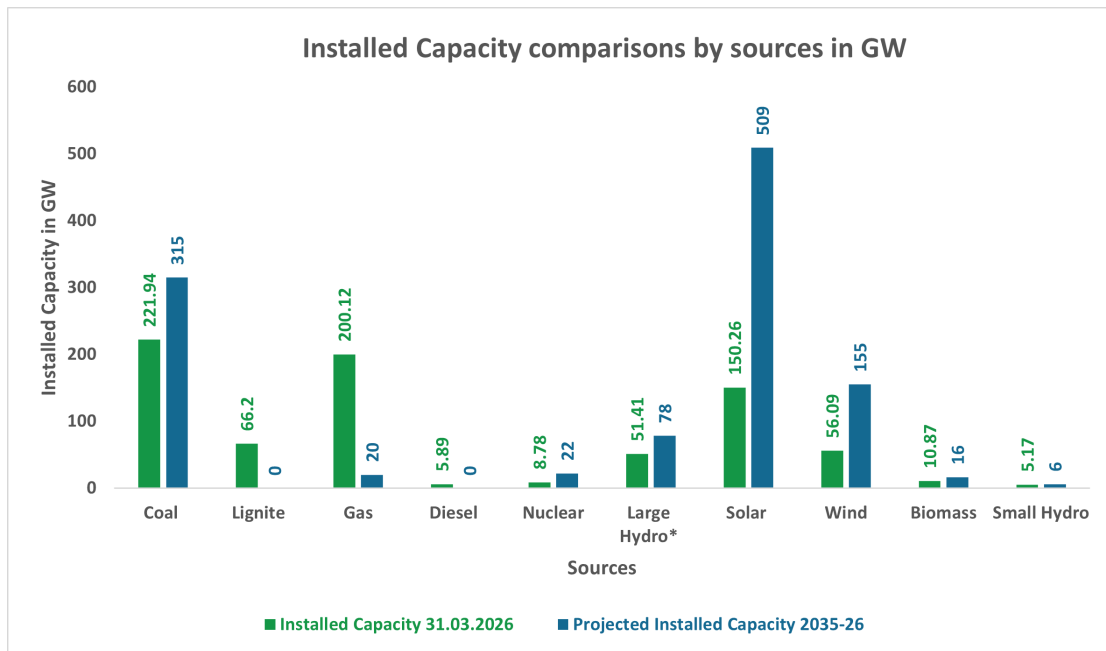

Year-wise Source-wise projected Installed Capacity requirement

Likely year-wise source-wise Net generation mix (BU)

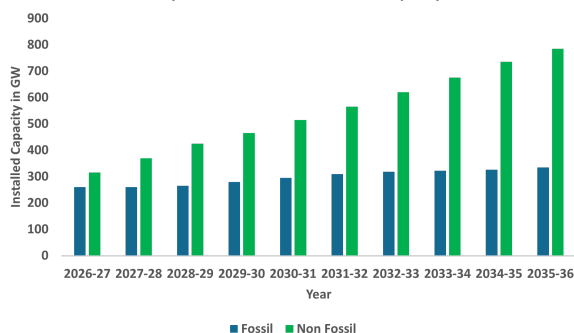

Installed Capacity comparisons by sources in GW

Large Hydro installed capacity figures for 2026 year also includes PSPs capacity. Lignite projected capacity is clubbed with coal for 2035-36

Likely Fossil vs Non-Fossil Installed Capacity

Fossil vs Non-fossil : % of total Net Generation

The study emphasizes the push towards non fossil fuel-based capacity addition, projecting the likely increase to be about 786GW by 2035-36 in capacity. It has also observed the need of storage (about 4-6 hours) to make higher RE penetration viable beyond 2030 and therefore places PSP as a comprehensive solution for meeting future storage capacity requirements at reasonable cost, along with ensuring grid reliability by providing frequency regulation, inertia and voltage support. The likely requirement of energy storage is about 174 GW/ 888 GWh by 2035-36 for energy shifting and facilitating increased RE integration. BESS is suitable for short-duration storage, and PSPs are suitable for long-duration storage.

Summary on Reliability Analysis Results

Using the Monte Carlo simulation i.e. a probabilistic modelling technique that uses repeated random sampling to evaluate the impact of uncertainty in complex systems. It captures the full range of possible scenarios and their probabilities, providing a more realistic picture. of system performance has been undertaken.

Value of Loss of Load Probability (LoLP) and Normalised Energy Not Served (NENS) at 0.2% and 0.05% respectively has been considered. These values are the same as taken for the preparation of the National Electricity Plan, brought out in May 2023. The analysis has been done for chart of Year-wise Source-wise projected Installed Capacity requirement. The following variations have been considered in the reliability-sensitive parameters. The results of the reliability analysis are also mentioned below

| Variations Considered for Monte Carlo Simulation | | |
|--|---------------------------------|----------------------------------|
| Parameter | Standard Deviation (σ) | Range of Variation (3σ) |
| Forced Outage of thermal generators (Coal and Gas) | 3.33% | $\pm 10\%$ |
| Block - wise Demand | 3.33% | $\pm 10\%$ |
| Block - wise Solar Generation | 3.33% | $\pm 10\%$ |
| Block - wise Wind Generation | 10% | $\pm 30\%$ |
| Block - wise Hydro Generation | 3.33% | $\pm 10\%$ |

| Results of Reliability Analysis | |
|---|---------|
| Parameter | 2035-36 |
| LoLP - Average | 0.18 |
| NENS - (%) - Average | 0.01 |
| Max ENS over iterations - MU | 12457 |
| Min ENS over iterations - MU | 0 |
| Max NENS over iterations - % | 0.37 |
| Min NENS over iterations - % | 0 |
| Max LoLP over iterations (% of total hours) | 3.52 |
| Min LoLP over iterations (% of total hours) | 0 |

Scenario II: Electricity demand projections as per recent trends

An additional scenario is envisaged for carrying out resource adequacy studies, wherein the recent trend of lower electricity demand growth has been considered. As a part of this scenario, the peak electricity demand and the annual electricity energy requirement projections as projected by the mid-term review of the 20th EPS study have been shifted by one year for the entire study horizon.

In this scenario, the projected peak electricity demand in 2035-36 reduces from 459 GW to 446 GW, while the electrical energy requirement reduces from 3365 BU to 3215 BU. Correspondingly, the total installed capacity requirement in 2035-36 is about 1054 GW compared to 1121 GW. The requirement of storage in this scenario is lower at about 128 GW compared to 174 GW in the scenario where demand had been considered as per mid-term review of 20th EPS.

Conclusions

- **315 GW** of coal-based generation capacity, which will continue to serve as the backbone of the power system for baseload supply.

- On the renewable front, significant capacity expansions to accelerate the clean energy transition are observable. This includes **78 GW** of hydroelectric power, which offers both renewable energy and grid balancing capabilities, **509 GW** of solar photovoltaic (PV) capacity, and **155 GW** of wind power.
- The plan also recognises the need for energy storage systems to shift the energy generated in high RE generation periods for use during low/no RE generation and high demand periods. Specifically, **94 GW** of Pumped Storage Plants (PSP) and **80 GW** of Battery Energy Storage Systems (BESS) are projected to be added.

Recommendations

- Planned Expansion of Non-Fossil Capacity
- Progressive Development of Energy Storage
- Maintaining Adequate Planning Reserve Margins (PRM)
- Enhancing Grid Flexibility and Infrastructure
- Ensuring Reliability through Resource Diversity
- Focus on Nuclear Capacity Development
